
6. HASHARRAYS

Hash arrays let you associate arbitrary Lisp objects (“hash keys”) with other objects (“hash values”), so you can get from key to value quickly. There are functions for creating hash arrays, putting a hash key/value pair in a hash array, and quickly retrieving the hash value associated with a given hash key.

By default, the hash array functions use `EQ` for comparing hash keys. This means that if non-symbols are used as hash keys, the exact same object (not a copy) must be used to retrieve the hash value. However, you can specify the function used to compare hash keys and to “hash” a hash key to a number. You can, for example, create hash arrays where `EQUAL` but non-`EQ` strings will hash to the same value. Specifying alternative hashing algorithms is described below.

In the description of the functions below, the argument `HARRAY` should be a hasharray created by `HASHARRAY`. For convenience in interactive program development, it may also be `NIL`, in which case a hash array (`SYSHASHARRAY`) provided by the system is used; you must watch out for confusions if this form is used to associate more than one kind of value with the same key.

Note: For backwards compatibility, the hash array functions will accept a list whose `CAR` is a hash array, and whose `CDR` is the “overflow method” for the hash array (see below). However, hash array functions are guaranteed to perform with maximum efficiency only if a direct value of `HASHARRAY` is given.

Note: Interlisp hash arrays and Common Lisp hash tables are the same data type, so functions from both may be intermixed. The only difference between the functions may be argument order, as in `MAPHASH` and `CL:MAPHASH` (see below).

(**HASHARRAY** *MINKEYS* *OVERFLOW* *HASHBITSFN* *EQUIVFN* *RECLAIMABLE* *REHASH-*
THRESHOLD) [Function]

Creates a hash array with space for at least *MINKEYS* hash keys, with overflow method *OVERFLOW*. See discussion of overflow behavior below.

If *HASHBITSFN* and *EQUIVFN* are non-`NIL`, they specify the hashing function and comparison function used to interpret hash keys. This is described in the section on user-specified hashing functions below. If *HASHBITSFN* and *EQUIVFN* are `NIL`, the default is to hash `EQ` hash keys to the same value.

If *RECLAIMABLE* is *T* the entries in the hash table will be removed if the key has a reference count of one and the table is about to be rehashed. This allows the system, in some cases, to reuse keys instead of expanding the table.

Note: `CL:MAKE-HASH-TABLE` does not allow you to specify your own hashing functions but does provide three built-in types specified by *Common Lisp, the Language*.

(**HARRAY** *MINKEYS*) [Function]

Provided for backward compatibility, this is equivalent to (`HASHARRAY` *MINKEYS* *'ERROR*) , i.e. if the resulting hasharray gets full, an error occurs.

INTERLISP-D REFERENCE MANUAL

(**HARRAYP** *X*) [Function]

Returns *X* if it is a hash array; otherwise **NIL**.

HARRAYP returns **NIL** if *X* is a list whose **CAR** is an **HARRAYP**, even though this is accepted by the hash array functions (see below).

(**PUTHASH** *KEY VAL HARRAY*) [Function]

Associates the hash value *VAL* with the hash key *KEY* in *HARRAY*. Replaces the previous hash value, if any. If *VAL* is **NIL**, any old association is removed (hence a hash value of **NIL** is not allowed). If *HARRAY* is full when **PUTHASH** is called with a key not already in the hash array, the function **HASHOVERFLOW** is called, and the **PUTHASH** is applied to the value returned (see below). Returns *VAL*.

(**GETHASH** *KEY HARRAY*) [Function]

Returns the hash value associated with the hash key *KEY* in *HARRAY*. Returns **NIL**, if *KEY* is not found.

(**CLRHASH** *HARRAY*) [Function]

Clears all hash keys/values from *HARRAY*. Returns *HARRAY*.

(**HARRAYPROP** *HARRAY PROP NEWVALUE*) [NoSpread Function]

Returns the property *PROP* of *HARRAY*; *PROP* can have the system-defined values **SIZE** (the maximum occupancy of *HARRAY*), **NUMKEYS** (number of occupied slots), **OVERFLOW** (overflow method), **HASHBITSFN** (hashing function) and **EQUIVFN** (comparison function). Except for **SIZE** and **NUMKEYS**, a new value may be specified as *NEWVALUE*.

By using other values for *PROP*, the user may also set and get arbitrary property values, to associate additional information with a hash array.

The **HASHBITSFN** or **EQUIVFN** properties can only be changed if the hash array is empty.

(**HARRAYSIZE** *HARRAY*) [Function]

Returns the number of slots in *HARRAY*. It's equivalent to (**HARRAYPROP** *HARRAY* ' **SIZE**).

(**REHASH** *OLDHARRAY NEWHARRAY*) [Function]

Hashes all hash keys and values in *OLDHARRAY* into *NEWHARRAY*. The two hash arrays do not have to be (and usually aren't) the same size. Returns *NEWHARRAY*.

(**MAPHASH** *HARRAY MAPHFN*) [Function]

MAPHFN is a function of two arguments. For each hash key in *HARRAY*, *MAPHFN* will be applied to the hash value, and the hash key. For example:

```
[MAPHASH A
 (FUNCTION (LAMBDA (VAL KEY)
  (if (LISTP KEY) then (PRINT VAL))]
```

will print the hash value for all hash keys that are lists. **MAPHASH** returns *HARRAY*.

HASHARRAYS

Note: the argument order for `CL:MAPHASH` is `MAPHEN HARRAY`.

(**DMPHASH** *HARRAY HARRAY ... HARRAY*) [NLambda NoSpread Function]

Prints on the primary output file `LOADable` forms which will restore the hash-arrays contained as the values of the atoms `HARRAY`, `HARRAY`, ... `HARRAY`. Example: (`DMPHASH SYSHASHARRAY`) will dump the system hash-array.

All `EQ` identities except symbols and small integers are lost by dumping and loading because `READ` will create new structure for each item. Thus if two lists contain an `EQ` substructure, when they are dumped and loaded back in, the corresponding substructures while `EQUAL` are no longer `EQ`. The `HORRIBLEVARS` file package command (Chapter 17) provides a way of dumping hash tables such that these identities are preserved.

Hash Overflow

When a hash array becomes full, trying to add another hash key will cause the function `HASHOVERFLOW` to be called. This either enlarges the hash array, or causes the error `Hash table full`. How hash overflow is handled is determined by the value of the `OVERFLOW` property of the hash array (which can be accessed by `HARRAYPROP`). The possibilities for the overflow method are:

the symbol <code>ERROR</code>	The error <code>Hash array full</code> is generated when the hash array overflows. This is the default overflow behavior for hash arrays returned by <code>HARRAY</code> .
<code>NIL</code>	The array is automatically enlarged by at least a factor 1.5 every time it overflows. This is the default overflow behavior for hash arrays returned by <code>HASHARRAY</code> .
a positive integer <i>N</i>	The array is enlarged to include at least <i>N</i> more slots than it currently has.
a floating point number <i>F</i>	The array is changed to include <i>F</i> times the number of current slots.
a function or lambda expression <i>FN</i>	Upon hash overflow, <i>FN</i> is called with the hash array as its argument. If <i>FN</i> returns a number, that will become the size of the array. Otherwise, the new size defaults to 1.5 times its previous size. <i>FN</i> could be used to print a message, or perform some monitor function.

Note: For backwards compatibility, the hash array functions accept a list whose `CAR` is the hash array, and whose `CDR` is the overflow method. In this case, the overflow method specified in the list overrides the overflow method set in the hash array. Hash array functions perform with maximum efficiency only if a direct value of `HASHARRAY` is given.

Specifying Your Own Hashing Functions

In general terms, when a key is looked up in a hash array, it is converted to an integer, which is used to index into a linear array. If the key is not the same as the one found at that index, other indices are

INTERLISP-D REFERENCE MANUAL

tried until it the desired key is found. The value stored with that key is then returned (from `GETHASH`) or replaced (from `PUTHASH`).

To customize hash arrays, you'll need to supply the "hashing function" used to convert a key to an integer and the comparison function used to compare the key found in the array with the key being looked up. For hash arrays to work correctly, any two objects which are equal according to the comparison function must "hash" to equal integers.

By default, Medley uses a hashing function that computes an integer from the internal address of a key, and use `EQ` for comparing keys. This means that if non-atoms are used as hash keys, *the exact same object* (not a copy) must be used to retrieve the hash value.

There are some applications for which the `EQ` constraint is too restrictive. For example, it may be useful to use strings as hash keys, without the restriction that `EQUAL` but not `EQ` strings are considered to be different hash keys.

The user can override this default behavior for any hash array by specifying the functions used to compare keys and to "hash" a key to a number. This can be done by giving the `HASHBITSFN` and `EQUIVFN` arguments to `HASHARRAY` (see above).

The `EQUIVFN` argument is a function of two arguments that returns non-NIL when its arguments are considered equal. The `HASHBITSFN` argument is a function of one argument that produces a positive small integer (in the range $[0..2^{16} - 1]$) with the property that objects that are considered equal by the `EQUIVFN` produce the same hash bits.

For an existing hash array, the function `HARRAYPROP` (see above) can be used to examine the hashing and equivalence functions as the `HASHBITSFN` and `EQUIVFN` hash array properties. These properties are read-only for non-empty hash arrays, as it makes no sense to change the equivalence relationship once some keys have been hashed.

The following function is useful for creating hash arrays that take strings as hash keys:

`(STRINGHASHBITS STRING)` [Function]

Hashes the string `STRING` into an integer that can be used as a `HASHBITSFN` for a hash array. Strings which are `STREQUAL` hash to the same integer.

Example:

```
(HASHARRAY MINKEYS OVERFLOW 'STRINGHASHBITS 'STREQUAL)
```

creates a hash array where you can use strings as hash keys.
